∃ ► < ∃ ►</p>

Starting from one consumer...

The Principal wants to incentivise the consumer to reduce the mean and the volatility of his consumption.

Moral Hazard: she observes the deviation consumption X of the Agent in continuous time, but not the effort ν he makes.

▶ Proved with Aïd and Touzi that she offers him a contract indexed on his deviation consumption:

$$\xi_{T} = \xi_{0} - \int_{0}^{T} \mathcal{H}(X_{s},\zeta_{s}) \mathrm{d}s + \int_{0}^{T} Z_{s} \mathrm{d}X_{s} + \frac{1}{2} \int_{0}^{T} \Gamma_{s} \mathrm{d}\langle X \rangle_{s} + \frac{1}{2} R_{A} \int_{0}^{T} Z_{s}^{2} \mathrm{d}\langle X \rangle_{s},$$

for an optimal choice of $\zeta = (Z, \Gamma)$.

Starting from one consumer...

The Principal wants to incentivise the consumer to reduce the mean and the volatility of his consumption.

Moral Hazard: she observes the deviation consumption X of the Agent in continuous time, but not the effort ν he makes.

▶ Proved with Aïd and Touzi that she offers him a contract indexed on his deviation consumption:

$$\xi_T = \xi_0 - \int_0^T \mathcal{H}(X_s, \zeta_s) \mathrm{d}s + \int_0^T Z_s \mathrm{d}X_s + \frac{1}{2} \int_0^T \Gamma_s \mathrm{d}\langle X \rangle_s + \frac{1}{2} R_A \int_0^T Z_s^2 \mathrm{d}\langle X \rangle_s,$$

for an optimal choice of $\zeta = (Z, \Gamma)$.

Results.

 Optimal contracting allows the system to bear more risk as the resulting volatility may increase;

Starting from one consumer...

The Principal wants to incentivise the consumer to reduce the mean and the volatility of his consumption.

Moral Hazard: she observes the deviation consumption X of the Agent in continuous time, but not the effort ν he makes.

▶ Proved with Aïd and Touzi that she offers him a contract indexed on his deviation consumption:

$$\xi_T = \xi_0 - \int_0^T \mathcal{H}(X_s, \zeta_s) \mathrm{d}s + \int_0^T Z_s \mathrm{d}X_s + \frac{1}{2} \int_0^T \Gamma_s \mathrm{d}\langle X \rangle_s + \frac{1}{2} R_A \int_0^T Z_s^2 \mathrm{d}\langle X \rangle_s,$$

for an optimal choice of $\zeta = (Z, \Gamma)$.

Results.

- Optimal contracting allows the system to bear more risk as the resulting volatility may increase;
- The control of the consumption volatility can lead to a significant increase of responsiveness.

Motivation & intuition A moral hazard approach A Stackelberg game with many consumers Optimal contract Principal's Problem

... and extend it to a mean-field of Agents

The producer is facing a Mean-Field (MF) of correlated consumers and optimise in mean.

Motivation & intuition A moral hazard approach A Stackelberg game with many consumers Optimal contract Principal's Problem

... and extend it to a mean-field of Agents

The producer is facing a Mean-Field (MF) of correlated consumers and optimise in mean.

Find a way for the Principal to benefit from dealing with this MF of consumers.

(日)

... and extend it to a mean-field of Agents

The producer is facing a Mean-Field (MF) of correlated consumers and optimise in mean.

Find a way for the Principal to benefit from dealing with this MF of consumers.

She knows the law of the consumption of the pool of consumers.

She can design a new contract in order to penalise / reward a consumer who makes less / more effort than the rest of the pool.

(日) (同) (日) (日)

... and extend it to a mean-field of Agents

The producer is facing a Mean-Field (MF) of correlated consumers and optimise in mean.

Find a way for the Principal to benefit from dealing with this MF of consumers.

She knows the law of the consumption of the pool of consumers.

She can design a new contract in order to penalise / reward a consumer who makes less / more effort than the rest of the pool.

Intuition.

Optimal contracts should consists of two parts:

A ⊡ ▶ A ⊡ ▶ A

... and extend it to a mean-field of Agents

The producer is facing a Mean-Field (MF) of correlated consumers and optimise in mean.

Find a way for the Principal to benefit from dealing with this MF of consumers.

She knows the law of the consumption of the pool of consumers.

She can design a new contract in order to penalise / reward a consumer who makes less / more effort than the rest of the pool.

Intuition.

Optimal contracts should consists of two parts:

• A classical part indexed on the deviation consumption of the Agent (previous contract);

・ロト ・ 同ト ・ ヨト ・ ヨト

... and extend it to a mean-field of Agents

The producer is facing a Mean-Field (MF) of correlated consumers and optimise in mean.

Find a way for the Principal to benefit from dealing with this MF of consumers.

She knows the law of the consumption of the pool of consumers.

She can design a new contract in order to penalise / reward a consumer who makes less / more effort than the rest of the pool.

Intuition.

Optimal contracts should consists of two parts:

- A classical part indexed on the deviation consumption of the Agent (previous contract);
- An additional part indexed on the law of the deviation consumption of others.

Setting and results Numerical results

A model for pollution regulation

A regulator tries to provide a system of electricity producers with incentives to

- use clean energies;
- invest to reduce the emission levels of other means of production.

A model for pollution regulation

- We place ourselves after the auction phase where producers have bid their cost functions.
- We are given a network structure where nodes are producers, with local demand *D*, production capacity *Q*, with power flows and transmission lines with losses *r*
- The role of the regulator is to decide the production levels q and energy flows ϕ^e at each node...

$$\begin{array}{c} D^1 = 5 \\ Q^1 = 6 \end{array} \underbrace{ \begin{array}{c} & \underline{\phi}^{1,2} = 0, \ \overline{\phi}^{1,2} = 1 \\ & \mathbf{f}_{1,2} = 0 \end{array} } \\ Q^2 = 0 \end{array} \\ \begin{array}{c} D^2 = 10 \\ Q^2 = 9 \end{array}$$

Figure: Example of the network constraints.

- ...and to choose a bonus/malus system to incentivise pollution reduction, through terminal payments ξ

イロト イポト イヨト イヨト

The setting

Each producer has an impact on the drift of the overall pollution L, thanks to their efforts.

$$L_t = L_0 + \sum_{i=1}^N \int_0^t (1 - \boldsymbol{a}_s^i) \boldsymbol{p}_i(\boldsymbol{q}_s^i) \mathrm{d}\boldsymbol{s} + \sigma W_t^a.$$

The regulator tries to minimise the social cost

$$\inf_{(q,\phi,\xi)\in\mathcal{C}} \mathbb{E}^{\mathbb{P}^{\mathfrak{s}^{\star}(q,\xi)}} \bigg[\sum_{i=1}^{N} \int_{0}^{T} c_{i}(q_{s}^{i}) \mathrm{d}s + \int_{0}^{T} \Lambda(L_{s} - \ell_{o}) \mathrm{d}s + \sum_{i=1}^{N} \xi^{i} \bigg],$$

where $a^{\star}(q,\xi)$ is a Nash equilibrium for the contracts (q,ϕ,ξ) .

The best-reaction function of each producer, given actions chosen by the others

$$V_0^i(a^{-i},\xi^i,q) := \sup_{a^i \in \mathcal{A}_i} \mathbb{E}^{\mathbb{P}^a} \bigg[U_A \bigg(\xi^i - \int_0^T \big(h_i(a^i_s) + c_i(q^i_s) \big) \mathrm{d}s \bigg) \bigg].$$

э

The setting

- Each producer has different technologies: he produces at the lowest marginal cost until the cheapest available technology is saturated.
- The network structure does not impact the resolution method, and only a finite dimensional optimisation problem.

< ロ > < 同 > < 回 > < 回 >

Main results

• The set of admissible remunerations can be represented as the terminal values of the family of processes

$$Y_t^{y,q,Z} = y + \int_0^t f(q_s, Z_s) \mathrm{d}s + \int_0^t Z_s \mathrm{d}L_s, \ t \in [0,T],$$

with the function $f:\mathbb{R}^N_+\times\mathbb{R}^N\longrightarrow\mathbb{R}^N$ given by

$$f^{i}(q,z) := h_{i}(a^{\star,i}(q,z)) + c_{i}(q^{i}) - z^{i} \sum_{j=1}^{N} (1 - a^{\star,j}(q,z)) p_{j}(q^{j}) + \frac{\rho \sigma^{2}}{2} (z^{i})^{2},$$

and

$$a^{\star,i}(q,z) := \operatorname{argmin}_{a \in A_i} \left\{ h_i(a) - z^i(1-a)p_i(q^i) \right\}.$$

Main results

 \bullet The value of the principal and the optimal contract are characterised by the HJB equation

$$-v_t - G(t,\ell,v_\ell,v_{\ell\ell}) = 0, \ (t,\ell) \in [0,T) \times \mathbb{R}, \ v(T,\ell) = 0, \ \ell \in \mathbb{R},$$

with $G:[0,T]\times \mathbb{R}\times \mathbb{R}\times \mathbb{R} \longrightarrow \mathbb{R}$ given by

$$G(t,\ell,\alpha,\gamma) := \inf_{(z,q,\phi) \in \mathbb{R}^N \times \hat{\mathcal{P}}_t} \left\{ g(\alpha,z,q,\phi) \right\} + \frac{1}{2} \gamma \sigma^2 + \Lambda(\ell-\ell_0),$$

and $g: \mathbb{R} \times \mathbb{R}^N \times \hat{P} \longrightarrow \mathbb{R}$ defined by

$$g(\alpha, z, q, \phi) := \sum_{i=1}^{N} \left(\alpha \left(1 - a^{\star, i}(q, z) \right) p_i(q^i) + h_i \left(a^{\star, i}(q, z) \right) + \frac{\rho \sigma^2}{2} (z^i)^2 + 2c_i(q^i) \right).$$

Main results

 \bullet The value of the principal and the optimal contract are characterised by the HJB equation

$$-v_t - G(t,\ell,v_\ell,v_{\ell\ell}) = 0, \ (t,\ell) \in [0,T) \times \mathbb{R}, \ v(T,\ell) = 0, \ \ell \in \mathbb{R},$$

with $G:[0,T]\times \mathbb{R}\times \mathbb{R}\times \mathbb{R} \longrightarrow \mathbb{R}$ given by

$$G(t,\ell,\alpha,\gamma) := \inf_{(z,q,\phi) \in \mathbb{R}^N \times \hat{P}_t} \left\{ g(\alpha,z,q,\phi) \right\} + \frac{1}{2} \gamma \sigma^2 + \Lambda(\ell-\ell_0),$$

and $g: \mathbb{R} \times \mathbb{R}^N \times \hat{P} \longrightarrow \mathbb{R}$ defined by

$$g(\alpha, z, q, \phi) := \sum_{i=1}^{N} \left(\alpha \left(1 - a^{\star, i}(q, z) \right) p_i(q^i) + h_i \left(a^{\star, i}(q, z) \right) + \frac{\rho \sigma^2}{2} (z^i)^2 + 2c_i(q^i) \right).$$

• This PDE has a unique viscosity solution with polynomial growth, which turns out to be $C^1 \longrightarrow$ enough to prove existence of an optimal contract

$$\xi^{\star} := y + \int_0^T f(q_s^{\star}, Z_s^{\star}) \mathrm{d}s + \int_0^T Z_s^{\star} \mathrm{d}L_s$$

Calibration

Inspired by the Chilean electricity market, we consider a network with three nodes representing the North, South and Centre regions of the country.

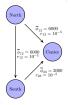

Figure: Characteristics of the network.

Demands	Value	Capacities	Value	Parameter	Value
D^1	3000 MW	Q^1	6000 MW	σ	200 tons of CO_2 per square root of time
D^2	1000 MW	Q^2	2000 MW	Т	90 days
D^3	6000 MW	Q^3	12000 MW	dt	1 hour

Table: Values of the parameters in the numerical simulations.

- < ∃ →

Calibration

• There are three technologies to produce power, namely coal, gas and solar. Each technology is assumed to be identical for each node.

Technology	Cost (dollars per MWh)	Pollution (tons of CO ₂ per MWh)
solar	0	0
coal	40	1
gas	80	0.5

Table: Cost and pollution of the technologies.

• Cost functions are piece-wise linear for each producer.

э

With regulation

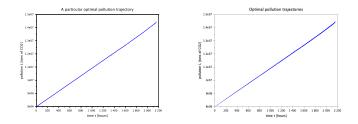

Figure: Pollution trajectories under regulation (30,000 simulations).

Contracts reduce the increment in the pollution levels by more than 30% percent, from 10,000,000 tons of CO_2 without regulation, to around 6,500,000 tons of CO_2 .

• • = • • = •

With regulation

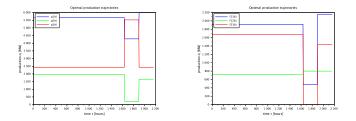

Figure: Production and transmission plans under regulation (30,000 simulations).

• First, Centre node produces exactly 2400 MW, with solar technology and no pollution. Leftover is provided by the others. Node in the North produces 5600 MW, while the South produces 2000 MW and receives a flow of 700 MW from the North.

With regulation

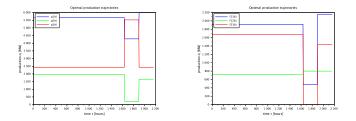

Figure: Production and transmission plans under regulation (30,000 simulations).

• First, Centre node produces exactly 2400 MW, with solar technology and no pollution. Leftover is provided by the others. Node in the North produces 5600 MW, while the South produces 2000 MW and receives a flow of 700 MW from the North.

• Second, node in the Centre cover most demand and produces 5500 MW. The node in the North contributes 500 MW and no flow is received from South. This occurs when the increase of pollution has been controlled for enough time and it becomes less costly to allow the node in the Centre to produce power.

With regulation

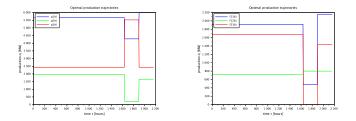

Figure: Production and transmission plans under regulation (30,000 simulations).

• First, Centre node produces exactly 2400 MW, with solar technology and no pollution. Leftover is provided by the others. Node in the North produces 5600 MW, while the South produces 2000 MW and receives a flow of 700 MW from the North.

• Second, node in the Centre cover most demand and produces 5500 MW. The node in the North contributes 500 MW and no flow is received from South. This occurs when the increase of pollution has been controlled for enough time and it becomes less costly to allow the node in the Centre to produce power.

• Third, we get back to a situation similar to the first period.
